DRUG UTILIZATION IN TREATMENT OF THYROID DISORDERS DURING PREGNANCY IN SERBIA

Olga HORVAT1,2, Zdenko TOMIĆ1,2, Vesna MIJATOVIĆ1,2 and Ana SABO1,2

Summary

Introduction. Depleted uranium radiation and pollution with polychlorinated biphenyls resulting from bombings the territories of Serbia as well as the additional long-term stress may have affected the function of thyroid gland. The objective of this study was to determine the trend of drug utilization in the treatment of thyroid dysfunction during pregnancy in Novi Sad. Material and Methods. Women who had given birth at the Department of Gynecology in 1989, 1999, 2007 and 2011 were interviewed during a one-month period about thyroid diseases in the pregnancy as well as the drugs they had taken. Results. Not a single pregnant woman was reported to have a thyroid disorder in 1989 and 1999, while in 2007 four women were reported to have a thyroid dysfunction. In 2011, fourteen out of 18 women with thyroid dysfunction were using levothyroxine and in most cases hypothyroidism was diagnosed as autoimmune Hashimoto thyroiditis. Conclusion. The study results suggest the necessity of performing more detailed analyses of the correlation between the frequency of the thyroid gland dysfunction and the effects of environmental pollution in Serbia. Key words: Thyroid Diseases; Pregnancy; Hashimoto Disease; Hypothyroidism; Propylthiouracil; Thyroxine; Risk Factors; Drug Therapy; Epidemiology; Serbia

Introduction

A wide variety of environmental agents affect the thyroid gland causing different thyroid function disorders and one of the well-known environmental catastrophes was the Chernobyl accident, when a significant correlation between the exposure to radioactive iodine $^{131}$ and the incidence of hypothyroidism was determined [1, 2]. This catastrophe led to the increased frequency of juvenile hypothyroidism in Belarus, the Russian Federation and Ukraine ten years later [3].

Acknowledgements

This work was supported by the Ministry of Science and Technological Development, Republic of Serbia (project No. 41012) and by the Provincial Secretariat for Science and Technological Development, Autonomous Province of Vojvodina (grant No. 114-451-3551/2013-02).

During the end stage of conflict period in the Balkans (in 1999), a partial or total destruction of industrial plants, military targets, infrastructure, as well as uncontrolled fires and explosions resulted in large amounts of hazardous organic matter that were generated and emitted into the environment, and the city of Novi Sad was recognized as an environmental hot spot by the United Nations Environment Programme and the United Nations Centre for Human Settlements [4]. About 73,000 tons of crude oil and oil products, including the transformer oil containing polychlorinated biphenyls (PCBs) were burned or leaked (UNEP/UNCHS Report, 1999) during the bombing of the Novi Sad oil refinery in 1999 [5]. The effect of PBC exposure on serum thyroid hormone levels is well documented in animals and humans [5–8]. Some of the studies have shown that the increased prevalence of some
thyroid antibodies may be related to the known immunomodulatory effects of PCBs [9, 10]. Depleted uranium (DU), an emerging environmental pollutant, was used as armor-penetrating ammunition in the Balkans conflict and was claimed to contribute to health problems [11, 12]. Studies investigating DU health effects at the cellular level or on animals exposed to DU suggest a possible influence on birth defects, immune system impairments, cancer risk etc. [13, 14].

Maintenance of normal thyroid function is essential for psychological and physiological well-being. Pregnant women with undiagnosed or inadequately treated hypothyroidism have an increased risk of miscarriage, preterm delivery, and severe developmental problems in their children [15, 16]. Therefore, the aim of our study was to determine the trend of thyroid function disorders through monitoring the utilization of drugs for the treatment of thyroid gland disorders in pregnant women, as the most vulnerable group of population in the city of Novi Sad, Serbia, before and after the conflict period in the Balkans.

Material and Methods

A survey was performed in Novi Sad, Serbia, a city with about 300,000 inhabitants, with only one Department of Gynecology and Obstetrics, The Regional Ethics Committee approved the survey. The study sample consisting only of women who had signed the informed consent form, thus showing that they were willing to participate in the survey.

Table 1 shows the trend in the drug utilization in treatment of thyroid dysfunction in pregnant women from 1988 to 2011 in Novi Sad.

In years 1988 and 1999 no drugs were used for treatment of thyroid dysfunction in pregnant women included in the surveys (296 and 100 pregnant women, respectively).

In 2007, four out of 423 pregnant women included in the study were reported to have thyroid dysfunction. Three (0.70%) out of four had hypothyroidism and all of them were administered levothyroxine replacement therapy, while one pregnant woman had hyperthyroidism.

In 2011, 18 out of 413 pregnant women included in the study were reported to have thyroid dysfunction.

Table 1. The prevalence of the thyroid dysfunction in pregnant women suffering from hypothyroidism and hyperthyroidism included in the survey at the Ward of Perinatology, Department of Gynecology and Obstetrics, Clinical Center Novi Sad in 1988, 1999, 2007 and 2011.

on. The replacement therapy of levothyroxine for the treatment of hypothyroidism was taken by 14 (3.39%) women during pregnancy out of 413 women included in the study, with the average duration of the treatment with levothyroxine sodium of 3.3±2.59 years. Autoimmune Hashimoto’s thyroiditis was diagnosed in 64.28% of them. The average duration of treatment with propylthiouracil was 1.6±0.94 years in four pregnant women with hyperthyroidism.

Discussion

Thyroid disorders are the second most common endocrine disorders found in pregnancy. However, data on epidemiology of thyroid diseases are scarce [19–21]. The epidemiology data vary widely, with overt hypothyroidism occurring in 0.3–0.5% [22] to 12.8% of pregnancies [22, 23]. Subclinical disorders appear to occur from 2–3% to 25% [21–24]. Therefore, the more accurate way of assessing the epidemiology of thyroid dysfunction is to follow the prevalence in time rather than to compare epidemiology between the countries.

In Novi Sad study the percentage of pregnant women taking drugs for hormonal disorders increased more than 4-fold between the last two study periods. Having in mind the significance of hypothyroidism on fetal development, such a high increase in the number of young pregnant women with hypothyroidism is alarming.

According to the published data, numerous reasons can trigger the autoimmune process affecting the thyroid gland, chemical factors and long-term stress being well recognized. The ammunition containing depleted uranium was used in military operations by NATO in all parts of Serbia during the Kosovo conflict in 1999. Public concern related to health consequences has been raised by the general belief that Novi Sad and the region of Vojvodina were contaminated by depleted uranium during the bombing. Some studies in animals have shown the immune modulation ability of DU. It can cause inappropriate apoptosis of murine (mouse) peritoneal macrophages, which can lead to both autoimmune problems and immunosuppression. The similarities between murine and human immune system genetics suggest that these findings may also apply to humans [25]. The analysis of 50 soil samples taken from the region of Vojvodina after the conflict showed slight increases in the activity of 137Cs, which has a negative impact on the environment, from 6.6 in 1989 to 8.2 Bq/kg in 2001 in the region of Novi Sad and from 23 to 31Bq/kg in the region of Vršac [26]. Most of 137Cs originates from Chernobyl disaster [27]. However, while the values in Novi Sad and Vršac slightly increased after 1999, in Subotica region which had not been bombed, with time the activity of 137Cs had the tendency to decline from 9Bq/kg in 1999 to 4.6Bq/kg in 2001 year. Contamination with inhaled DU was proved by the excretion of DU isotopes in the urine of exposed military personnel seven years after the Balkans conflict according to Durakovic (2001) [11].

Škrtić and Miljević investigated the soil pollution at the oil refinery in Novi Sad following the destruction of crude oil and its products in storage tanks during the Kosovo conflict by taking the soil samples from several fields of the oil refinery [28]. At some locations the presence of PCBs, another important environment pollutant, indicated the burning of additives stored at the refinery site. The contamination with PCBs presents a great environmental risk, especially for drinking water (the oil refinery of Novi Sad is located just 0.5 km upstream of bank filtration wells used for the city’s water supply) due to the potential migration of identified pollutants by groundwater to infiltration galleries [29]. In adults, adolescents and children from highly PCB-exposed areas the concentration of PCB in blood samples correlated negatively to the levels of circulating peripheral thyroid hormones [30]. The levels of PCBs in the environment are associated with reduced thyroid hormone levels in the pregnant women [31, 32]. Prenatal or postnatal exposure of humans or animals to PCBs can result in hormonal changes and neurodevelopmental deficits [33, 34]. The long-term exposure to heavy environment pollution among the employees of PBCs factory in Slovakia resulted in a significant increase of autoantibodies against thyroid peroxidase (TPO Ab) as well as a higher prevalence of autoantibodies against thyroglobulin (Tg Ab) and autoantibodies against TSH (TSHR Ab) especially in female employees compared to the control group [35].

Numerous other reasons can affect the prevalence of dysfunction of thyroid gland, long-lasting stress being one of them [36]. Studies including soldiers after the war and victims of abuse have shown abnormal values of TSH, triiodothyronine (T3) and thyroxine (T4), with mostly decreased values of thyroid hormones. The effects of chronic stress during the civil war in Serbia have not been investigated yet. Its long lasting consequences in combination with environment pollutants includes not only disturbances of homeostasis, but also a potentially deadly disease such as an increased number of malformations in newborns and different forms of cancer in adults [2, 37, 38].

Limitation of the Study

A shortcoming of this study is the absence of data on the prevalence of thyroid disorders in pregnant women, namely the hypothyroidism, which results from insufficient epidemiology data in Serbia. The translation of results of comparative research of thyroid disorders prevalence is hard to conduct due to differences in definition and samples of population as well as the fact that the use of unique series of diagnostic criteria for the prevalence of these disorders are necessary. The data about the possible causes of environment pollution and stress on hypothyroidism in pregnancy
are scarce, and conclusions about their influence on pregnancy are insufficient so far.

Conclusion

Our study suggests a significant increase of symptomatic autoimmune thyroid disease, namely Hashimoto’s thyroiditis, in pregnant women in Novi Sad region during the last decade. Although the reasons have been discussed, they are still not known. Further follow up of this trend and detailed study of possible reasons are necessary. Due to the significance of proper treatment of hypothyroidism in pregnant women, it is recommended to introduce routine testing of all pregnant women in order to diagnose subclinical cases of pregnancy to start treatment on time.
