Abstract

Obesity is a chronic, complex, relapsing disease impacting healthcare systems and the economy worldwide. We aim to analyze the utilization trends of antiobesity drugs, and their reimbursement status on drug lists of health insurance funds (HIF) in selected European countries. The DDD/1000 inhabitants/day methodology is used for utilization trend analysis, where data from official national utilization reports were used. For the reimbursement status analysis of 5 antiobesity drugs (orlistat, semaglutide, liraglutide, naltrexone/bupropion, setmelanotide), the websites of national health insurance funds (HIF) of 22 European countries were screened. Trend analysis revealed fluctuation for almost all antiobesity drugs (the highest decrease seen for orlistat in Serbia, and the highest increase for liraglutide in Croatia). Novel antiobesity drugs show an increasing utilization trend in almost all the countries. In two out of three European countries,

antiobesity drugs are not covered by the HIF. Slovenia and Denmark reimburse most of the antiobesity drugs. The Netherlands is the only country where the cost of setmelanotide is paid by the HIF. Our results emphasize the importance of prioritizing the introduction and implementation of new strategies and reimbursement scheme models in global and national antiobesity policies.

Key words: obesity, drug consumption, DDD/1000 inhabitants/day, health insurance fund, reimbursement status

Introduction

Obesity is a chronic, complex relapsing disease defined as a Body Mass Index (BMI) above 30 kg/m², whereas a BMI in the range of 25.0–29.9 is classified as pre-obesity (overweight). According to the World Health Organization (WHO), nutritional status categories based on the BMI are: *underweight*: < 18.5; *normal weight*: 18.5–24.9; *pre-obesity*: 25.0–29.9; *obesity class I*: 30.0–34.9; *obesity class II*: 35.0–39.9; *obesity class III*: > 40.0), while surgical classification defines three subtypes: *severe obesity* (> 40.0), *morbid obesity* (40.0–50.0) and *super obesity* (> 50.0) (1-4).

It is considered that overweight and obesity have reached epidemic proportions (5), where about 12% (5/41 million) of adult deaths caused by non-communicable diseases are driven by a BMI \geq 25.0 (6). By 2035, 3.3 billion adults and 40% of children (5-19 years) are expected to be overweight or obese, and if no intervention is made, the prevalence of overweight and obesity in adults in the European region is expected to reach 71% (6). The global economic cost is predicted to be over US\$ 3 trillion by 2030, and even six times more by 2060 (US\$ 18 trillion) (7), where global economy will be reduced by over US\$ 4 trillion in 2035, nearly 3% of global gross domestic product (8).

It is recognized that obesity is a growing worldwide problem for healthcare systems, and its global burden represents a threat to public health, undermining social and economic development, with the potential to increase inequalities (2, 9). A health services response to obesity must focus at three levels in the health system: primary (the general population), secondary (people at risk of obesity), and tertiary (established/controlled obesity) prevention (10).

Some of the most common comorbidities of obesity are diabetes mellitus type 2 (DMT2), prediabetes, coronary disease, polycystic ovarian syndrome (PCOS), dyslipidemia, metabolic syndrome, obstructive sleep apnea, osteoarthritis (OA), carcinoma, gastroesophageal reflux disease (GERD), and psychological disorders (3), where in practice it is hard to distinguish between comorbidities and conditions related to obesity as its complications.

Divino et al. quantified the cost of burden of 13 complications related to obesity (obstructive sleep apnea, PCOS, heart failure with preserved ejection fraction (HFpEF), urinary incontinence, OA of the knee, DMT2, prediabetes, asthma, psoriasis, GERD, hypertension, dyslipidemia, musculoskeletal pain), where the most costly complications were OA of the knee (\$3,697/year), HFpEF (\$3,586/year), and psoriasis (\$2,711/year), showing that obesity-related complications are a significant contributor to the economic burden of obesity and highlighting the need for the treatment of obesity (11). Another study showed that 2/3 of the costs of obesity are related to indirect costs (69% to premature death, 31% to productivity loss), and only 32% are caused by medical and non-medical care costs (12).

The management of obesity is a complex procedure and includes changes in eating habits, physical activity, psychological support, pharmacotherapy, and/or surgical

treatment (3, 9). Anti-obesity drugs are indicated for patients with a BMI ≥ 30 kg/m² or a BMI ≥ 27 kg/m² with comorbidities (3), but it is not recommended to use them alone, without combining different approaches (nutritional, cognitive-behavioral, pharmacological, and surgical) (9). Drugs for obesity with marketing authorization issued by the European Medicines Agency are: orlistat, liraglutide, semaglutide, naltrexone/bupropion, and additionally, phentermine/topiramate, and tirzepatide in the United States of America (3, 13-16).

This paper aims to analyze utilization trends and reimbursement status of antiobesity drugs in selected European countries.

Material and methods

For the purposes of utilization trend analysis, a dataset based on utilization expressed in daily defined dose (DDD)/1000 inhabitants/day (official methodology recommended by the WHO) was created using the official reports of the competent regulatory bodies of the Republic of Serbia (period: 2007–2022) (17), the Republic of Croatia (period: 2007–2022) (17), Norway (period: 2007–2022) (19-24), Estonia (period: 2010–2022) (24–30), Latvia (period: 2010–2022) (25–27, 32), Lithuania (period: 2010–2018) (25-27) and Finland (period: 2018–2021) (33). These countries and covering periods were selected based on the public availability of their annual reports on drug utilization expressed as DDD/1000 inhabitants/day, in line with the WHO methodology. Utilization data levels in these reports may differ between countries (e.g., wholesaler level, pharmacy level). Accordingly, the extent of usage was not the focus of this research; instead, we analyzed the trend of antiobesity drug utilization over time.

We analyzed the trend of antiobesity drug utilization using the joinpoint regression software (34-35). The joinpoint regression method has been used to analyze drug utilization; it identifies the year(s) (points) when a significant annual percent change (APC) occurs over the defined period (36).

The selected utilization data (DDD/1000 inhabitants/day) were data on the 1st ATC level for A - Alimentary tract and metabolism, on the 2nd ATC level for A08 - Antiobesity preparations, excl. diet products, and on the 5th ATC level for drugs used to treat obesity, which are (were) available in the selected European countries: A08AA10 sibutramine, A08AA12 setmelanotide, A08AA62 bupropion and naltrexone, A08AB01 orlistat, A10BJ02 liraglutide, A10BJ06 semaglutide. Utilization data for liraglutide and semaglutide also included utilization for DMT2 indication, since utilization reports provide information on the international non-proprietary name (INN), not on the brand name (liraglutide is the active substance for Victoza (DMT2 indication), and Saxenda (obesity indication), semaglutide for Ozempic (DMT2 indication), and Wegovy (obesity indication).

For the reimbursement status analysis, a dataset was created using publicly available information from the 22 Health Insurance Fund websites of the European

countries (37-58), with the cutoff date of March 2024. Drugs authorized by the European Medicines Agency (EMA) for the indication of obesity were screened: orlistat (brand names: Alli (previously Orlistat GSK), Xenical), semaglutide (brand name: Wegovy), liraglutide (brand name: Saxenda), naltrexone/bupropion (brand name: Mysimba), and setmelanotide (brand name: Imcivree).

Results

Drug utilization trend analysis

Drug utilization trend analysis on the 1st ATC level (A - alimentary tract and metabolism) shows growth in all seven analyzed countries, with the highest growth in Estonia (2010-2016, APC=11.15, $p < 0.05$), and lowest in Estonia (2016-2022, APC =2.56). Trends of decrease show no statistical significance. Interestingly, the same country showed the highest and also the lowest growth trend in different periods, where additional analysis is needed to find the cause of this trend shift.

Sibutramine is the drug that was used from 2007 to 2011 in 3 of the selected countries (Croatia, Norway, and Serbia), with an increase in utilization only in Serbia (APC=126.16, $p < 0.05$). Moreover, naltrexone/bupropion was utilized in only 3 countries (Estonia, Norway, Serbia), starting in 2017, and a significant utilization increase was seen in Norway and Serbia, with more than 100 annual percent change seen (APC=108.13, $p < 0.05$; APC=134.52, $p < 0.05$, respectively). Orlistat and liraglutide are the only drugs that were utilized in all 7 countries, with fluctuation in utilization for both drugs. Orlistat showed a statistically significant increase only in Norway (2007-2009, APC=37.74, $p < 0.05$), while the most extreme decrease was seen in Serbia and Estonia (2019-2022: APC= -59.49, $p < 0.05$; 2010-2012: APC=-54.95, $p < 0.05$, respectively). It is interesting that in Norway a period of increase of more than 30% was followed by a similar decrease in orlistat utilization.

Semaglutide is the only drug having a statistically significant increase in utilization in all countries (except Croatia), while setmelanotide is the only drug (of all analyzed) having no utilization in the selected countries. We represent the joinpoint regression analysis model results in Table I, and graphically in Figures 1-6.

In the Table III, we provide utilization data from seven countries (Croatia, Estonia, Finland, Latvia, Lithuania, Norway, and Serbia) that we used in our analysis.

Reimbursement lists status

We analyzed the reimbursement status of antiobesity drugs authorized by the EMA in 22 European countries. In only 36% of countries (8/22), the health insurance fund (HIF) reimburses at least one antiobesity drug. In Croatia, only orlistat (Xenical) is reimbursed, while in Ireland only liraglutide (Saxenda) is reimbursed. Semaglutide (Wegovy) is reimbursed only in Denmark and Switzerland.

The HIF covers liraglutide (Saxenda) and naltrexone/bupropion in Denmark, Finland, the Netherlands, and Slovenia. Setmelanotide is only reimbursed in the Netherlands, where the retail price of this drug is 2,997.50 EUR.

In Slovenia, four out of six analyzed drugs are reimbursed, except setmelanotide and semaglutide (Wegovy), even though semaglutide indicated for DMT2 (Ozempic, Rybelsus) is reimbursed. In Serbia, only novel antiobesity drugs are authorized by the National Medical Agency but not covered by health insurance.

Table II summarizes all the results indicating European countries where antiobesity drugs costs are covered by the HIF.

Discussion

Sibutramine was the drug authorized in Europe in 2001, followed by serious cardiovascular adverse effects reporting (including death), which caused its withdrawal from the European market in 2010 (59).

Since naltrexone/bupropion is a novel antiobesity drug that has been authorized in Europe for less than 10 years, an increasing trend in its utilization is expected in most countries, as demonstrated by our results (60). On the other hand, orlistat has been used in practice for about 25 years (authorized by the EMA in 1998) (61), being almost the

only drug indicated for obesity for decades, and a decreasing trend in its utilization may be caused by the increased utilization of novel drugs.

Novel drugs (liraglutide, semaglutide, naltrexone/bupropion) showed an upward trend in utilization from 2019 in almost all the selected countries.

Even though many pharmaco-economic studies showed the cost-effectiveness of novel drugs compared to different approaches (e.g., diet and exercise, no treatment...) (62-65), in most European countries, antiobesity drugs are still not reimbursed by health insurance funds, meaning patients must pay for them out of pocket. The “best situation” is that in Slovenia and Denmark, where almost all drugs are reimbursed, while in almost 70% of European countries no obesity drug is covered by the HIF.

The safety of antiobesity drugs was a concern in the past, and many of them were withdrawn from the market, e.g.: dexfenfluramine and fenfluramine due to cardiac valvulopathy; rimonabant due to an increased risk of depression and suicidal ideation, and sibutramine as mentioned before; lorcaserin was removed due to cancer (66-68). The effectiveness of antiobesity drugs was a barrier as well, since, in clinical practice, antiobesity drugs were prescribed to prevent or improve related chronic diseases (hypertension, DMT2, cardiovascular risk, etc.) (66-68).

Our results showed no unique utilization trends in any of the selected European countries. Some drugs showed an increase in utilization in one country but a decrease in another; in one country, there was first a trend of increase and then a decrease in utilization. According to the available publications, the reason for low utilization of antiobesity drugs may lie in low patient adherence, physicians not feeling comfortable prescribing them due to safety and efficacy, lack of knowledge of the availability of novel drugs, having limited experience with these drugs, or not recognizing that drugs should be used in obesity management (66-67). Moreover, most of these drugs are not reimbursed by the HIF, or if they are, they have additional prescribing limitations, bearing high drug costs for the patients (66-68). Increased utilization of novel drugs (e.g. naltrexone/bupropion and liraglutide) may be influenced by the increased awareness of obesity as a chronic, relapsing disease in the last years, emphasizing its economic impact worldwide (7-8). To the best of the authors' knowledge, this is the first study focused on utilization and reimbursement status for antiobesity drugs, including novel drugs, in European countries.

The main limitations of this study are that utilization is analyzed only in the European countries where data are publicly available; data levels (pharmacy, wholesaler) are not the same between countries, so direct DDD/1000inhabitans/day utilization comparison is not possible, and only trend analysis is. In addition, the data for semaglutide and liraglutide include utilization for both indications, obesity and DMT2, so it was not possible to make a distinction between the two and determine which indication influences utilization the most.

Our utilization trend analysis results show fluctuation for almost all antiobesity drugs, which may be caused by the fact that, in the majority of European countries, they

are paid by the patient. Considering that obesity poses significant health and economic risks to almost every country worldwide, it is crucial to introduce and implement global and local policies, along with new reimbursement scheme models.

Kratak sadržaj

Gojaznost je hronična, kompleksna bolest koja se ponovo javlja (relaps) i utiče na zdravstvene sisteme i ekonomiju širom sveta. Cilj nam je da analiziramo trendove potrošnje lekova protiv gojaznosti, kao i status refundacije tih lekova na listama lekova fondova zdravstvenog osiguranja (FZO) u odabranim evropskim zemljama. Za analizu trenda potrošnje korišćena je metodologija DDD/1000 stanovnika/dan, gde su korišćeni podaci iz zvaničnih nacionalnih izveštaja o potrošnji. Za analizu statusa refundacije za 5 lekova protiv gojaznosti (orlistat, semaglutid, liraglutid, naltrekson/bupropion, setmelanotid), pregledani su sajtovi nacionalnih FZO u 22 evropske zemlje. Analiza trenda je otkrila fluktuacije za skoro sve lekove protiv gojaznosti (najveći pad zabeležen za orlistat u Srbiji, a najveći porast za liraglutid u Hrvatskoj). Novi lekovi protiv gojaznosti pokazuju trend rasta upotrebe u skoro svim zemljama. U dve od tri evropske zemlje lekove protiv gojaznosti ne pokriva FZO. Slovenija i Danska refundiraju troškove većine lekova protiv gojaznosti. Holandija je jedina zemlja u kojoj trošak setmelanotida plaća FZO. Naši rezultati naglašavaju važnost davanja prioriteta uvođenju i implementaciji novih strategija i modela šema refundacije u globalnim i nacionalnim politikama usmerenim protiv gojaznosti.

Ključne reči: gojaznost, potrošnja lekova, DDD/1000 stanovnika/dan, fond za zdravstveno osiguranje, status refundacije
