Abstract: The main objective of this study was to evaluate the effect of age (A) and the intensity of the boars' utilization (s) on the phenotypic variability of ejaculate volume (VOL) and sperm motility (MO). The study included 274 ejaculates of Large White boars (LW). Boars were divided into six classes according the age when the ejaculate was taken (10-13, 14-17, 18-21, 22-25, 26-29 and ≥ 30 months). Semen samples were analyzed during four seasons (spring, summer, autumn, winter). The intensity of the use of boars was seen as the impact of the group (class) of intervals between two successful collections (I; ≤ 5 , 6, 7, 8, 9-10, 11-13, 14-21 days). Data processing was performed using the GLM procedure using the statistical package *SAS 9.1.3 (SAS Inst. Inc., 2002-2003)*. Average values of VOL, MO, I, A, were: 178.94 ml, 90.35%, 9.37 days and 655.93 days. The effect of boars on both studied sperm traits was highly significant ($p < 0.001$). The volume of ejaculate varied under the influence of boar age ($p < 0.001$) and season ($p < 0.01$). The effect of I on VOL and MO was not significant ($p > 0.05$). Traits VOL and MO varied ($p < 0.001$) between boars which indicated the need for individual control of each of boars used for artificial insemination. The highest VOL was determined in boars at the age of 26 to 29 months, and the difference to the boars aged 10-13 months was 62.70 ml ($p < 0.001$). No statistically significant differences in regard to VOL between boars older than 17 months (from class 3 to 6) were recorded. The highest differences between winter and spring period were determined in mean values of VOL (32.15 ml; $p < 0.01$). In the winter period, boar ejaculate volume was lower than in the autumn (-26.57 ml) and the difference determined was statistically significant ($p < 0.05$).

Keywords: pigs, boar, ejaculate volume, motility

Introduction

In modern pig production, artificial insemination has completely suppressed the natural mating, so that the evaluation of quantitative and qualitative characteristics of ejaculate is a standard procedure in breeding technology. Rating quantitative and qualitative characteristics of semen has high economic importance to the pig breeders (*Smital, 2010*).

In populations of pigs which are under continuous selection program there is a tendency for the better utilization of boars, good production performance, which is reflected in the preparation of a large number of doses per ejaculate of optimal fertile ability. In addition to sperm concentration, semen volume and sperm motility determine fertility of doses produced per ejaculate. Motility is the most important trait that affects fertilization capacity of sperm (*Feitsma, 2009*). Rating motility of spermatozoa is the most important parameter of sperm (*Kunowska-Słószarz and Makowska, 2011*).

Variability of ejaculate volume and sperm motility is influenced by various genetic and paragenetic factors. Properties of boar sperm vary under the influence of breed, age, season, intensity of use, and other factors (*Stančić et al., 2003; Frangež et al., 2005; Okere et al., 2005; Wolf and Smital, 2009a; Wolf and Smital, 2009b; Kondracki et al., 2009; Smital, 2010; Kunowska-Słószarz and Makowska, 2011*).

The aim of this study was to determine how age, intensity of use of boars and annual season affect the phenotypic variability of ejaculate volume and sperm motility.

Material and methods

The study included a total of 274 ejaculates from 6 boars of breed Large White (LW).

Ejaculates from boars grown under production conditions for a period of two years (October 2010 - September 2012) were examined. The data on the volume of ejaculate (VOL, ml) and sperm motility (MO %) of boars were used. Ejaculate volume was measured with an accuracy of ± 10 ml, and sperm motility evaluation was performed by a subjective method, observing the native sperm sample under a microscope with a standard magnification (visual score). The average number of ejaculates per boar was 45.67, and boars with less than five ejaculate were excluded from the analysis. Ejaculates with VOL below 50 ml or MO less than 70% were not included in the study. At each taking of ejaculate collection) the age of the boar was recorded, and the average age was calculated as the average of all ages at the individual collections of boars. Boars were divided into six classes according to their age when the ejaculate was taken (10-13, 14-17, 18-21, 22-25,

26-29 and ≥ 30 months). Semen samples were analyzed during four seasons of a year (spring, summer, autumn, winter). The intensity of the use of boars (I) was observed as the influence of groups (classes) of the interval between two successful collections ($\leq 5, 6, 7, 8, 9-10, 11-13, 14-21$ days). Ejaculates from boars that were preceded with the interval between two consecutive successful collections of 3 and 4 days, because of the small number, were attached to the group (class) of ≤ 5 days.

Data analysis was performed using the GLM procedure using the statistical package *SAS 9.1.3 (SAS Inst. Inc., 2002-2003)*. The following statistical model was used:

$$Y_{ijklm} = \mu + B_i + A_j + S_k + I_l + \varepsilon_{ijklm},$$

where: Y_{ijklm} - observed sperm property, μ - general population average, B_i - the effect of the boar ($i=1,2,3,\dots,6$), A_j - the effect of boar age class ($j=1,2,3,\dots,6$), S_k - the effect of season ($k=1,2,3,4$), I_l - the effect of utilization intensity ($l=1,2,3,\dots, 7$) and ε_{ijklm} – random error. Testing (comparison) of Least Square Means (LSMeans) values was done using t- test.

Results and discussion

The mean age of studied boars was 655.93 days or 21.86 months (Table 1). The mean volume of ejaculates was 178.94 ml, sperm motility was 90.35%. The interval between successive collections of boars ranged from 3 to 21 days, or in average 9.37 days.

Table 1. The average values (\bar{X}) and variability of studied properties of boar ejaculates

Variable	NE	\bar{X}	SD	Min	Max
Volume of ejaculates (VOL, ml)	274	178.94	51.30	50	300
Motility (MO, %)	274	90.35	5.69	70	100
Interval between successive collections (I, day)	274	9.37	3.79	3	21
Age of boars of the collection (A, day)	274	655.93	239.33	289	1628

NE- Number of ejaculates; SD- Standard Deviations; Min- Minimum; Max- Maximum

The average value for VOL of ejaculate in this study was lower compared to the research by *Kunowska-Slósarz and Makowska (2011)* (178.94 compared to 255.25 ml) for the same breed of boars. In regard to MO, the average value in the present paper was higher (+11.20%) compared to the value obtained by aforementioned authors. The high average value of MO in this study was the result of exclusion of ejaculates with value below 70%, and subjectivity in the visual assessment of sperm motility in the ejaculate. In the study by *Sutkevičienė and*

Žilinkas (2004), the average age of the boars was 18.79 ± 5.59 months, with an average volume of ejaculate from 261.60 ± 134.25 ml, and the percentage of subjective sperm motility of $71.49 \pm 6.42\%$.

The impact of factors on varying of sperm properties is presented in Table 2. Calculated coefficients of determination indicated that the variability of the VOL compared to the MO, can be explained to a greater extent as influenced by factors observed.

Both properties of sperm varied under the influence of boars (B, $p < 0.001$), indicating a need for individual control of each of boars used for artificial insemination. Unlike the MO whose variability was not influenced by other observed factors, the VOL varied under the influence of age (A, $p < 0.001$), and the season (S, $p < 0.01$). The intensity of use of boars (I, $p > 0.05$) did not significantly affect the variability of VOL and MO in sperm.

Table 2. Effect of variables included in the model

Variable	Semen traits			
	VOL		MO	
	p	R ²	p	R ²
Boars (B)	***	0.361	***	0.143
Classes of age of boars (A)	***		ns	
Season (S)	**		ns	
Interval between successive collections (I)	ns		ns	

VOL- Volume of ejaculates; MO- Motility; R²- Coefficient of determination;

** - $p < 0.01$; *** - $p < 0.001$

The results of this study pertaining to the significance of the factors included in the model are partly consistent with the research of *Smital (2010)* in which all the studied factors (breed-center, year, month, and year x month, boar age, interval between collections and boars) have influenced ($p < 0.001$) all the analyzed properties of the sperm.

Both studied properties of sperm varied between boars (Table 3). Boar number 4 had the highest VOL, and the difference compared to the boars number 2 and 3, was 41.57 and 31.57 ml, respectively ($p < 0.001$). The difference between boars with the highest and lowest MO (boars 6 and 5) was 8.86% ($p < 0.01$). Boar 5 had lower average sperm motility than boars 4 and 2 (-8.38 and -8.69%). The differences established between the mean values of MO between stated boars were highly statistically significant ($p < 0.01$).

Table 3. Effect of boars on semen properties

Boars	LSMeans±SE	
	VOL (ml)	MO (%)
1	169.03±9.31	90.19±1.20
2	156.79±7.06 ^A	91.69±0.91 ^{Aa}
3	166.79±5.05 ^A	88.71±0.65 ^a
4	198.36±4.63 ^B	91.38±0.60 ^{b, Aa}
5	170.42±16.29	83.00±2.09 ^{Bb}
6	179.81±8.09	91.86±1.04 ^{Aa}

VOL- Volume of ejaculates; MO- Motility; a, b- $p < 0.05$; Aa, Bb- $p < 0.01$; A, B- $p < 0.001$

If both properties are observed, the highest number of doses with an average motility of spermatozoa of 91.38% was possible to produce from ejaculates taken from boar 4.

The lowest VOL of ejaculate (Table 4) was at the age of boars of 10-13 months (class 1). Lower mean values of the volume of ejaculate (from 134.59 to 169.97 ml) were observed in age classes 1 to 3 (boars at the age of 10 to 21 months), higher values (from 191.04 to 197.29 ml) were observed in the class of 4 to 6 (boars at the age of over 21 months).

The main reason for the increase of VOL with the age of boars is increase in the size and mass of the testes, causing increase in the production of sperm. According *Kanokwan (2011)* one of the reasons for increasing sperm production from a biological point of view is the increase in the number of Sertoli cells in the testes. According to *Ford et al. (2006)* the primary factor in daily sperm production is the number of Sertoli cells, which is associated with the testicular mass. The highest VOL was determined in boars at the age of 26 to 29 months, and the difference compared to the boars aged 10-13 months was 62.70 ml ($p < 0.001$). Boars of age group 2 had lower average volume of ejaculate compared to boars in group 4 (-36.66 ml, $p < 0.05$), group 6 (-39.55 ml, $p < 0.05$) and group 5 (-42.91 ml, $p < 0.001$). No statistically significant differences were established in VOL between boars older than 17 months (from class 3 to 6). In populations of pigs which are in a program of continuous selection and breeding, due to high selection pressure, boars are commonly used in the reproduction for 6-8 months, so they do not achieve maximum VOL values. In regard to MO, there were no statistically significant differences ($p > 0.05$) in mean values between the age groups of boars.

Table 4. Least Square Means values and differences between classes of age of the boars

Age of the boars		LSMeans±SE	
Classes	Month	VOL (ml)	MO (%)
1	10-13	134.59±10.25 ^A	89.92±1.32
2	14-17	154.38±8.34 ^{a, AA}	90.46±1.08
3	18-21	169.97±7.05	87.87±0.91
4	22-25	191.04±7.30 ^{B, b}	88.27±0.94
5	26-29	197.29±8.53 ^{B, BB}	89.54±1.10
6	≥30	193.93±7.79 ^{B, b}	90.77±1.00

VOL- Volume of ejaculates; MO- Motility; a, b- $p < 0.05$; A, B i AA, BB- $p < 0.001$

There is a tendency of increase of ejaculate volume with increasing age of boars. Similar conclusions have been made in the study by *Stančić et al. (2003)*, *Banaszewska and Kondracki (2012)*. Ejaculate volume increases until the age of about two years, and remains more or less constant (*Wolf and Smital, 2009a; Wolf and Smital, 2009b*), so that our research was in accordance with the research of these authors, since the higher VOL values were observed in boars older than 21 months. The results of this study are consistent with research results of *Smital (2009)*, in which an increase of sperm parameters with age boars was observed, but achieving of the maximum values of the parameters of boar semen was at the age of 3.5 years.

The results of the present study pertaining to the effect of boar age on MO are consistent with the research of *Šerniené et al. (2002)* in which the differences between the age groups of boars were recorded, but not significant.

The effect of the season on the variability of VOL was highly significant (Table 2, $p < 0.01$), and LSMean values during different seasons, according the analyzed properties of the sperm, are presented in Table 5.

The highest VOL was in the summer period (187.34±7.75 ml), and lowest in the winter period (155.19±6.37 ml). The highest difference in mean values was recorded between these two annual seasons (32.15 ml; $p < 0.01$). In winter the volume of ejaculates was lower than in the autumn (-26.57 ml) and observed difference was statistically significant ($p < 0.05$). Low value of VOL during winter may be due to inadequate housing conditions caused by low temperatures. The lowest MO was during the winter period (88.58%), but when it comes to the variability of these properties, the differences between seasons were not significant.

Table 5. Effect of season on variability of the semen traits

Season	LSMeans±SE	
	VOL (ml)	MO (%)
Spring	169.85±6.33	89.50±0.81
Summer	187.34±7.75 ^{Aa}	89.10±1.00
Autumn	181.76±7.29 ^a	90.71±0.94
Winter	155.19±6.37 ^{Bb, b}	88.58±0.82

VOL- Volume of ejaculates; MO- Motility; a, b- $p < 0.05$; Aa, Bb- $p < 0.01$

The results of this study, which related to the value of the VOL in the spring period (169.85 ml), and which was below the annual average (178.94 ml), are partially similar to studies by *Okere et al. (2005)*, *Kondracki et al. (2009)*, *Wolf and Smital (2009a)*, who established, in the spring, the lowest volume of ejaculate in the studied breeds. Partial similarity is also with the results of research *Kunowska-Słószarz and Makowska (2011)*, given that in the study of the authors in the period January-June VOL values determined were below the annual average, and above average values from August to December.

In Table 6, LSMeans values are presented according to groups (classes) of the interval between two successful collections. There were differences between the groups (classes) but they were not significant ($p>0.05$). A small number of ejaculate that were preceded by the interval between two consecutive successful collections of three or four days contributed to a reduction in the variability of sperm properties influenced by this factor.

Table 6. Effect of the interval between successive collections (I)

Interval between successive collections (I, day)	LSMeans±SE	
	VOL (ml)	MO (%)
≤5	159.65±8.80	88.34±1.13
6	182.30±7.88	89.80±1.01
7	173.91±8.37	89.16±1.07
8	175.94±7.15	89.23±0.92
9-10	169.47±6.26	89.91±0.80
11-13	173.97±7.05	89.66±0.91
14-21	179.50±7.67	90.21±0.99

VOL- Volume of ejaculates; MO- Motility

Contrary to the present study, in the research carried out by *Frangež et al. (2005)*, the differences in the characteristics between the sperm of different frequencies of use of boars were established. The research by *Wolf and Smital (2009a)* has shown small increase in ejaculate VOL with extension of I from two to seven days, while for longer intervals changes were insignificant, and small changes have been observed when it comes to the variability of MO.

Conclusion

Variability in the ejaculate VOL compared to the MO can be largely explained by the influence of the analyzed factors .

Ejaculate volume varied under the influence of boars (B, $p<0.001$), age (A, $p<0.001$), and the season (S, $p<0.01$). MO variability was only under a significant effect of boars (B, $p<0.001$). The intensity of use of boars (I, $p>0.05$) in this study did not show a significant effect on the studied properties of semen.

Variability between boars in the studied traits of sperm is high, indicating the need for individual control of each of boars used for artificial insemination.

There is a tendency of VOL increase with the age of boars. No statistically significant differences were determined between VOL values of boars older than 17 months (from class 3 to 6). However, given that in the selected population of pigs, boars are used in the reproduction for 6 to 8 months, this tendency has no practical significance.

Given that there are differences in the VOL according to seasons, it is necessary to provide boars during the year with the adequate housing conditions and optimum microclimate parameters.

Varijabilnost volumena ejakulata i pokretljivosti spermatozoida u zavisnosti od starosti i intenziteta korišćenja nerasta

R. Savić, M. Petrović, D. Radojković, Č. Radović, N. Parunović, M. Pušić, R. Radišić

Rezime

Osnovni cilj istraživanja bio je da se oceni uticaj starosti (A) i intenziteta korišćenja nerasta (I) na fenotipsku varijabilnost volumena ejakulata (VOL) i pokretljivosti spermatozoida (MO). Istraživanjem je bilo obuhvaćeno 274 ejakulata nerasta rase veliki jorkšir (LW). Nerasti su prema starosti kada je uzet ejakulat podeljeni u šest klasa (10-13, 14-17, 18-21, 22-25, 26-29 i ≥ 30 meseci). Ejakulati su analizirani tokom četiri godišnje sezone (proleće, leto, jesen, zima). Intenzitet korišćenja nerasta posmatran je kao uticaj grupe (klase) intervala između dva uspešna skoka (I; $\leq 5, 6, 7, 8, 9-10, 11-13, 14-21$ dan). Obrada podataka izvršena primenom GLM procedure uz pomoć statističkog paketa *SAS 9.1.3 (SAS Inst. Inc., 2002-2003)*.

Prosečne vrednosti VOL, MO, I, A bile su: 178,94 ml, 90,35%, 9,37 dana i 655,93 dana. Uticaj nerasta na obe ispitivane osobine sperme bio je vrlo visoko značajan ($p < 0,001$). Volumen ejakulata varirao je pod uticajem starosti nerasta ($p < 0,001$) i sezone ($p < 0,01$). Uticaj I na VOL i MO nije bio značajan ($p > 0,05$). Osobine VOL i MO varirale su ($p < 0,001$) između nerasta što ukazuju na potrebu

individualne kontrole svakog nerasta koji se koristi za veštačko osemenjavanje. Najveći VOL utvrđen je kod nerasta pri uzrastu od 26 do 29 meseci, a razlika u odnosu na neraste uzrasta 10-13 meseci bila je 62,70 ml ($p < 0,001$). Nisu ustanovljene statistički značajne razlike VOL između nerasta starijih od 17 meseci (od klase 3 do 6). Između zimskog i letnjeg perioda godine utvrđena je najveća razlika srednjih vrednosti VOL (32,15 ml; $p < 0,01$). U zimskom periodu volumen ejakulata nerasta bio je manji nego u toku jeseni (-26,57 ml) i utvrđena razlika je bila statistički značajna ($p < 0,05$).
