Introduction: In many aspects of STEMI patient treatment there are the clear guideline according to many scientific evidence from excellent designed and performed large randomized clinical studies. However there is still some gray zones of knowledge and scientific fields in which exist no answered questions.

Case report: Male patient age 68 has been admitted to Cardiology Clinic, Institute for Cardiovascular Diseases of Vojvodina, Sremska Kamenica due to typical chest pain and electrocardiography (ECG) signs of STEMI anterolateral region. The patient is hospitalized in center for PPCI with time delay of 210 minute, dominantly due to no adequate organization of medical service. Immediate after the admission primary percutaneous intervention (PPCI) was performed at distal tip of venous graft for obtuse branch of LCX with drug eluting stent (DES) implantation with the minimum intra-hospital time delay. Hospital course was complicated by heart failure, atrial fibrillation, and thrombus in the left ventricle.

Conclusion: Timely diagnosis of STEMI and good organization of medical service at all level is the key to successful care, and the prevention of time delay in establishing diagnosis and adequate therapeutic activities remains an imperative in the treatment of patients with STEMI.

Key words STEMI, percutaneous coronary intervention, time delay, treatment.
2018 at 9.59 hour and 6 p.m. as well as at 19.30 hour our display at Figures 1, 2 and 3. During the period of observation in regional hospital some diagnostic work up was performed. Laboratory tests performed after the chest pain started revealed enlarged level of high sensitive troponin I and CPK MB isoenzyme (TnI 33639 ng/l, CK-MB 246,9 ng/ml). According to this clinical scenario the patient gets 300 mg of aspirin oral.

According to ECG displayed at Figure 2 and 3, at 19.39 hour by telephone has been consulted on duty cardiologist in our institution. During telephone consultation ECG recordings has been presented to our on duty cardiology via Viber technology. Immediate transfer to our cardiology Clinic was suggested.

The patient arrived to our emergency department (ED) at 21.30 hour or some 3.5 hour or 210 minutes after the symptoms of STEMI started.

At the admission in our hospital the patient was dyspnoic with mild increased respiratory rate of 18-20/min., with basal rales on lungs with oxygen saturation of 91%. Blood pressure 140/80 mmHg, sinus rhythm rate 90/min. According to this findings patient at the moment at admission was in Killip 2 functional class.

The patient was pretreated in our ED with loading dose of ticagrelor of 180 mg oral, 20 mg of i.v. furosemide. Immediate after he was transferred to catheterization laboratory for emergency coronarography.
At 21:46 hour the patient was in catheterization laboratory and 5 minutes later 6 Fr arterial sheet was introduced in right radial artery. Coronarography revealed significant stenotic lesions of native left anterior descending coronary artery (LAD) with 70-90% stenosis. The native RCA and obtuse marginal branch were with chronic total occlusions (CTO). Venous graft for RCA was patent with no stenotic lesion and infarct related artery was targeted as distal segment of venous graft for obtuse marginal branch of LCx at the point of attachment to obtuse marginal branch.

Immediate after was performed primary percutaneous intervention (PPCI) at distal tip of venous graft for obtuse branch of LCx with drug eluting stent (DES) implantation, with optimal result. TIMI flow 3 was achieved. During the procedure 380 ml of contrast agent has been used, 24 minute of X-ray exposure and total irradiation of 703 mGy.

After the procedure due to progression of heart failure to level of acute pulmonary oedema, the patient was transferred to intensive coronary care unit (ICCU). His vital signs deteriorate rapidly, respiratory rate 25-28/min., heart rate of 100/min., oxygen saturation to 88 %, and lactate level of 2.2 mmol/l. With additional 40 mg of furosemide, spironolactone of 50 mg, oxygen via facial mask with flow of 4 l/min. was added.

All this measures gives the results and rapid clinical stabilisation was achieved. After 12 initial hours of treatment the patient was clinical stable enough and transferred to semi-intensive intensive department.

Echocardiography at the first day revealed significant reduction of both systolic diastolic function of left ventricle. Initial estimation was on about 25-30 % left ventricle ejection fraction (LVEF) with highly suspicious apical thrombotic material (Figure 5). According to that finding additional transpulmonal contrast echocardiography was performed (Figure 6). Contrast echocardiography enable more accurate endocard visualization and confirmed thrombotic material in apical segment of left ventricle and even worse systolic function of left ventricle with approximate EFLV around 20 %.

Due to visualized thrombus with high embologenic potential, low molecular weight heparin (LMWH) was introduced in therapeutic dose. First dose of beta blocker was introduced in dose of 1,25 mg orally bisoprolol and zofenopril 3,25 mg twice daily.

At the second day or 30 hour after the admition clinical state deteriorate. The patient start to be mental agitated and atrial fibrillation with rapid ventricular rate appeared (Figure 6). After the introduction of amiodarone and additional beta blocker therapy successful conversion to sinus rhythm has been achieved. How-
ever paroxysmal events of atrial fibrillation and flutter were noticed and at 3rd and 4th day of hospitalization. All those rhythm disturbances have been successfully converted with medicament interventions. By estimating the thrombotic and potential bleeding risk with CHA2DS2-VASc score value of 4, and HAS-BLED score of 2, triple antithrombotic therapy was introduced according to at least two indications, atrial fibrillation and visualized thrombus in left ventricle. The antiplatelet therapy was switched to clopidogrel 75 mg, and LMWH followed by oral anticoagulant therapy with warfarin. Further clinical course went without complications. According to lack of evident ongoing ischemia there was no indication for repeat coronaryography or additional revascularization procedure. Heart team indicate additional functional investigation for eventual rest coronary ischemia in the follow up by stress echocardiography examination. The patient was discharged from hospital after 11 days of hospital stay, with no clinical complains in stable heart sinus rhythm. Triple antithrombotic therapy (clopidogrel, aspirin, warfarin) was proposed for at least 1 month. Other therapy consists beta blockers (bisoprolol), amiodarone, ACE inhibitor (zofenopril), statin (rosuvastain), diuretic (furosemide + spironolactone) and insulin and proton pump inhibitor ( pantoprasol).

Discussion

Timely diagnosis of STEMI is key of successful treatment, starts with first medical contact (FMC). In accordance with modern European guidelines, 12-channel ECG must be done at the place of FMC, with ten minutes of delay. In addition, ECG monitoring is recommended with all patients with suspicious for STEMI. Routine blood samples for cardiac-specific enzymes is also recommended, but its results or not needed to start reperfusion therapy.2 7

In this case, patient had immediately reported chest pains, and time from FMC to first ECG was less than ten minutes. However, clearly ECG signs of STEMI was not recognized and caused delay initial time delay added with not necessary laboratory diagnostic workout, not recommended in case of evident ECG changes such as ST elevation. Considering that PPCI was feasible within 120 min, transfer to primary PCI center was indicated. Patient was admitted at ED after 3.5 hours from reported chest pains. Patient was transferred from ED, directly to catheterization laboratory. This approach is strongly recommended according to some data from hospitals with high volume in PPCI in United States.8 9

From the above, we can conclude that total ischemic time was 3 hour and 45 min, whereby patient delay in this case was minimal. Delay to establish definite diagnosis and transportation time was unacceptable too long. According to guidelines recommendations for intra hospital delay in PCI center have to be as shorter as possible. In our case the longest time delay was due to adequate analysis of ECG records and the transport organization of the patient to PPCI center. Knowing that nearest PPCI center is within 7 km away from regional hospital, the total time delay due to medical system of 210 minutes was extreme long.

Coronarography, graftography and in the same act PPCI, was performed by radial approach, with implantation of DES in venous graft for obtuse branch of LCx. Transradial approach in PPCI is feasible and safer in patients with aorto-coronary by-pass grafts. Percent of positive outcome of intervention is similar between transradial and transfemoral approach, but transradial approach is connected with lower rank of severe vascular complications.10

Interventional cardiologists often choose radial approach because of experience and smaller risk of bleeding complications.11 14

Decision of DES implantation is made according to relevant guidelines. Latest generations of DES showed greater safeness and even better efficiency, especially when it comes to reducing risk of stent-thrombosis and reinfarction.2 15

Based on meta-analysis results, routine thrombus aspiration during PPCI is not recommended, but in case of larger thrombus mass after opening of coronary artery one should consider.16

The use of GP IIb / IIIa inhibitors should be considered as an auxiliary treatment strategy before, during and after the PCI, if there is no flow in the open artery or thrombotic complications are present.17 In this case, after the intervention an optimal result was achieved and without thrombotic complications, the therapy was not applied.

According to relevant guidelines, patients with STEMI and multi vessel disease, revascularisation of lesions on non-infarction arteries should be considered before discharge.18 19 20 Because of significant changes of LAD,
in this case, ambulatory functional estimation is indicated in irrigation area of LAD.

A further course of patient hospitalization is complicated by heart failure, the onset of stagnant blood in the left ventricle and the presence of microthrombus between trabecula, and then by the onset of paroxysm of atrial fibrillation.

In accordance with relevant guidelines, therapy for the treatment of acute heart failure was applied, with the use of therapeutic doses of parenteral anticoagulant therapy.

Following guidelines for STEMI 2017. within treatment of heart failure, oxygen therapy is recommended with SpO2 < 90%. Although the benefit of oxygen therapy in patients with STEMI, who are hypoxic is undisputed, the use of oxygen in non-hypoxic patients is still controversial.21 A new randomized study showed that routine oxygen administration in normoxic patients with STEMI did not show any benefit over a one-year mortality.22 There are practically no clear randomized studies that support the routine use of oxygen in patients with acute IM, and the harmful effect cannot be excluded.23 Because patient had several episodes of paroxysmal atrial fibrillation and suspected microthrombus in the left ventricle, in addition to the application of dual antiplatelet therapy, oral anticoagulant therapy (OAT) was also added, which is confirmed by calculated scores (HAS-BLED and CHA2DS2-VASc). According to relevant guidelines, triple therapy should be considered - (aspirin, clopidogrel, OAT) for one to six months to patients who have an indication for taking OAT, and who have been under PCI, regardless of the type of stent.

If there is a large ischemic risk due to acute coronary syndrome or other anatomic/procedural characteristics, it is necessary to consider giving triple therapy for more than a month, up to 6 months.24 Suspension of antiplatelet therapy should be considered after 12 months.25 However, despite a large number of studies, it remains unclear what is the best decision of antithrombotic therapy in patients who have indication for OAT and antithrombotic therapy at the same time.

Conclusion

Timely diagnosis of STEMI, and good organization of medical service at all level is the key to successful care, and the prevention of delay remains an imperative in the treatment of patients with STEMI, in order to reduce the occurrence of complications and to improve the clinical course and outcome of the disease.

Uvod: U mnogim aspektima tretmana STEMI pacijenata postoje jasna uputstva prema mnogim naučnim dokazima iz odlično dizajniranih i izvedenih velikih randomizovanih kliničkih studija. Međutim i dalje postoje tzv. sive zone u saznanjima i naukom neodgovorena pitanja.

Prikaz slučaja: Muškarac starosti 68 je primljen na Kliniku za kardiologiju, Institut za kardiovaskularne bolesti Vojvodine, Sremska Kamenica zbog tipičnih bolova u grudima i elektrokardiografskih (EKG) znakova STEMI anterolateralne regije. Pacijent je hospitalizovan u centru za PPCI sa kašnjenjem od ukupno 210 minuta nakon početka simptoma STEMI-a, dominantno zbog kašnjenja u organizaciji zdravstven službe. Urađenom primarnom perkutanom koronarnom intervencijom (PPCI) na distalnom kraju venskog grafta za LCx sa implantacijom lekom obloženog stenta (DES) ostvaren je sa minimalnim gubitkom intrahospitalnog vremena zbrinjavanja. Bolnički tok je komplikovan srčanom insuficijencijom, atrijalnom fibrilacijom i trombom u levoj komori.

Zaključak: Pravovremena dijagnoza STEMI- i dobra organizacija svih delova zdravstvenog sistema je ključ uspešnog lečenja, a prevencija vremena odlaganja postavljanja dijagnoze i ispravnih terapijskih postupaka, ostaju imperativ u lečenju bolesnika sa STEMI.

Ključne reči: STEMI, perkutana koronarna intervencija, vreme odlaganja, lečenje
