Ogilvie Syndrome in a COVID-19 Patient with Pneumonia, Absolute Tachyarrhythmia and Heart Failure: a Case Report

Zoran Matković,1 Nataša Đekić Matković1

Abstract

The COVID-19 pandemic has recently spread worldwide presenting primarily in form of pneumonia. Gastrointestinal manifestations such as nausea, vomiting, diarrhoea and abdominal pain are less common than respiratory symptoms. However, critically ill patients may develop digestive complications including acute pseudo-obstruction of colon - Ogilvie syndrome. Gastrointestinal symptoms can manifest before the onset of typical respiratory symptoms. Common mucosal immune response underly both-pulmonary and gastrointestinal manifestations (high expression of angiotensin-converting enzyme 2 receptors). This article described a 75-year old female patient who arise Ogilvie syndrome during viral bilateral pneumonia induced by COVID-19. Patient also had an absolute tachyarrhythmia and heart failure. Diameter of caecum, ascending and transverse colon was 12 to 14 cm. The walls of this segment of large bowel were deserosed, with threatening perforation. Right colectomy was performed. Nine days after the surgery, despite all therapeutic measures taken, there was a fatal outcome due to pulmonary thromboembolisation.

Key words: Ogilvie syndrome; COVID-19; Pneumonia; Heart failure; Gastrointestinal manifestations.

Introduction

The COVID-19 pandemic has recently spread worldwide and became a global challenge to public health.1, 2 Pneumonia and other respiratory diseases are most common form of COVID-19, but, last months, gastrointestinal (GI) symptoms are recognised as one of the leading extrapulmonary characteristics of the virus.1 In regard to the GI system COVID-19 present with nausea, vomiting, diarrhoea and abdominal discomfort and pain.3-6 GI symptoms expression are less frequent than pulmonary (about 20 %)7, 8, 11 but Chinese patients demonstrated that more than half (50.5 %) had at least one of the GI symptom.3 Hypomotility-associated consequences were developed in half of the patients, with 46 % of them developed ileus diagnosed clinically and radiologically.10 SARS-CoV-2 virus can be found in faeces.11, 12, 19 Recent studies have reported that GI symptoms can be presented before respiratory manifestation.3, 5, 8 In cases where nasal swab is negative, faecal testing can be advised in patients with digestive manifestation.9 One study suggested that 9/76 cases of positive COVID-19 infection were identified in patient conferred with abdominal pain without respiratory symptoms at the time of COVID-19 pandemic.33 COVID-19 patients with GI disease had higher le-
Case history

A 75 years old female patient was admitted in our hospital due to fever, cough, myalgia, anorexia, fatigue and dyspnoea. First symptoms occurred seven days before admission. Peripheral oxygen saturation was 90 % and body temperature was in normal range (36.2 °C). Blood pressure was slightly elevated (150/90 mmHg). Fast Ag test was negative, while PCR test and serologic test (increase IgM antibody) were positive. Blood analysis performed are presented in Table 1. High level of CRP, D-dimer, neutrophilia and lymphopenia were detected. Transaminase levels were in normal range (AST 21, ALT 45). X-ray of chest showed shadows in lower parts of both lungs - Infiltratio basalis bilateralis.

Antibiotics (Ceftriaxone, 2 x 2 g), low molecular weight heparins (LMWH), crystalloid solutions, vitamin and oxygen therapy was given.

Abdominal discomfort appeared ten days after admission, patient started vomiting. First native abdominal X-ray showed meteorism, without aero-liquids levels, but next two X-rays revealed signs of ileus of large bowel (Figure 1 and 2). After consultative examination by a surgeon conservative treatment was attempted (Bowel rest, NG tube, electrolyte correction, neostigmine). A patient was transferred to surgical department for COVID-19 positive patients.

Later that day, in the evening, on examination, palpation indicated acute abdomen. It was suspected that patient developed mesenteric thrombosis and intestine necrosis due to absolute arrhythmia.

NLR: Neutrophile/lymphocyte ratio; MLR: Monocyte/lymphocyte ratio; LDH: Lactate dehydrogenase; CRP: C-reactive protein
Laboratory and clinical data tracking are essential for increasing treatment success in COVID-19 patients. Laboratory findings are accompanied with severe form of disease. C-reactive protein, D-dimer and NLR have the most important influence on COVID-19 prognosis. GI epithelia with SARS CoV-2 host-cell receptors and high expression of Angiotensin converting enzyme receptor type 2 could explain abdominal organs partaking. GI manifestation can be explained with SARS-CoV-2 intestinal tropism. Bowels and glandular epithelial cells of GI can be affected with SARS-CoV-2. Faecal-oral transmission is a potential way of SARS-CoV-2 transmission. Physicians and researchers have conflicted opinions on ACE inhibitors therapy discontinuation due to increasing number and activity of ACE-2 receptors.

Loss of parasympathetic spinal control of intestine motility can be one of diseases characteristics. Acute colonic pseudo-obstruction (ACPO) syndrome (Ogilvie) is characterised with colon part of transverse colon and decedent colon were without pathological changes. No mechanical causes of the cessation of the passage was seen. It was not possible to suppress content without rupturing of the bowel. It was concluded that was acute pseudo obstruction of large bowel - the Ogilvie syndrome. Extended right hemicolectomy was performed. Nine days after the surgery, despite all therapeutic measures taken, there was a fatal outcome due to pulmonary thromboembolisation.

Pathological findings - macroscopic description
The colon was with a thinned wall, about 0.1 cm. Lumen was dilated, mucosa was yellow-green, with reduced folds.

Microscopic description
The intestinal villi were broad and swollen. Mucosa was partially missing and necrotic. The fibrin exudate was seen above mucosa. Transmurally, especially in submucosa, extremely dilated blood and lymph vessels as foci of bleeding and an inflammatory infiltrate dominated by neutrophils. Fibrous-purulent exudate was also present on the serous surface of the colon.

Discussion
Therefore, an emergency surgery was performed. Intraoperative finding: whole right colon and biggest part of transverse colon (2/3) were extremely dilated (megacolon, lumen diameter was between 12-14 cm) (Figure 3-5). Colon segment walls were deserosed, with threatening perforation. Small
distension in absence of mechanical obstruction and it is induced by deteriorated autonomic nervous system. In this case, there is not any mechanical barrier in lumen or in wall of colon or extraluminal compression. Colonoscopic decompression is one of effective therapeutic options in patients with this syndrome. Abdominal computed tomography (CT) is the gold standard imaging modality in these cases. In this case, CT was not performed due to technical issues.

Patients with COVID-19 surgical appearance can have mesenteric inflammation or congestion that can simulate appendicitis or ileus diagnosis. Impact of perioral nutrition is very important in patients with anorexia as leading symptom followed by diarrhoea, nausea and vomiting and abdominal discomfort.

Probiotics are recommended from China National Health commission in treatment of patients with severe form of COVID-19 because they can reduce intestinal disbalance with bacterial displacement and consequently reduce secondary infections. The caloric intake should be more than 1500-2000 calories, with 75 to 100 g of protein per day. Oral diet is desirable in patients who are capable to eat. Otherwise, enteral feeding via nasogastric or nasojejunal tube may be useful. This patient had a small oral intake due to loss of appetite. A few studies suggested that the threshold must be reduced for supplemental or full parenteral nutrition as those types of nutrition are not safe or well tolerated.

In one study, 58 of 141 patients had digestive hypomotility, although these GI complications could be associated with metabolic and electrolyte disturbances or pharmacologic adverse events, experienced in patients with severe form of disease. Severe acute respiratory syndrome initiated by thrombosis small vessel or viral enteropathy requires further investigation.

Histopathological specimen of resected bowel shows COVID-19 initiated microthrombosis, inflammatory infiltrate and necrotic fields leading to GI perforation. In case of the presented patient similar findings were registered.

Doctors treating COVID-19 patients should be attentive of these consequences and be watchful in cases where gastrointestinal symptoms required surgical consultation. In critically ill patients there is high frequency of GI complications, due to intestinal ischaemia group of patients can required urgent surgery.

**Conclusion**

Early recognition and management of GI complications in COVID-19 patients, primarily conservative, are extremely important to reduce rates of mortality. As evidence for GI involvement increase, a suspicion for COVID-19 infection must be managed in all cases of patients with abdominal discomfort requiring surgical consultation. Ogilvie syndrome is one of possible GI manifestations, and one must think about this because delayed diagnosis often can lead to poor disease course and fatal outcome.
